8.5.2005

# DSS in source separation

## Whitening

Neuroscience

## Denoising

Procedural formulation of prior information

## DSS in real-world problems

Fast algorithms

DSS in Climate research

# DSS in feature extraction

Features from natural images

Hierarchical feature extraction

- Invariances

- Nonlinear feature expansion

- Expectation-driven learning

DSS and neuroscience

- Neocortical structure

- Role of attention in goal-directed learning

Conclusion

# Selection of information

- ▶ In many real-world problems there are plenty of data with a lot of structure.

# Selection of information

- ▶ In many real-world problems there are plenty of data with a lot of structure.
- ▶ Usually only part of the structure is interesting.

# Selection of information

- ▶ In many real-world problems there are plenty of data with a lot of structure.
- ▶ Usually only part of the structure is interesting.
- ▶ Which part is interesting depends on the goals.

# Selection of information

- ▶ In many real-world problems there are plenty of data with a lot of structure.
- ▶ Usually only part of the structure is interesting.
- ▶ Which part is interesting depends on the goals.
- ▶ Source separation and feature extraction are similar selection processes when data dimensionality is high.

# Local learning

- ▶ Fast learning rules are often local: weight modification needs local information only.

# Local learning

- ▶ Fast learning rules are often local: weight modification needs local information only.
- ▶ Hebbian and anti-Hebbian learning are prime examples of local learning rules: weight change is proportional to pre- and post-synaptic activation.

## Part I

### DSS in source separation

- **Situation:** interesting and uninteresting components are observed in mixtures (linear or nonlinear).

## Part I

### DSS in source separation

- ▶ **Situation:** interesting and uninteresting components are observed in mixtures (linear or nonlinear).
- ▶ **Task:** separate the interesting sources.

# Example

Let's consider a simple source separation task: a source should be recovered from two linear mixtures of two sources.

# Example

Let's consider a simple source separation task: a source should be recovered from two linear mixtures of two sources.

- ▶ Source 1 (target) changes slower in time than the other interfering source.

# Example

Let's consider a simple source separation task: a source should be recovered from two linear mixtures of two sources.

- ▶ Source 1 (target) changes slower in time than the other interfering source.
- ▶ Both sources are observed on two channels, but source 1 is relatively stronger on channel 2 and vice versa.

## Problem: how to avoid interference

- ▶ The contribution of one source to the channels is called the mixing vector  $\mathbf{a}$ . The mixing vectors of different sources form the mixing matrix  $\mathbf{A}$

$$\mathbf{x} = \sum_i \mathbf{a}_i s_i = \mathbf{A} \mathbf{s}$$

## Problem: how to avoid interference

- ▶ The contribution of one source to the channels is called the mixing vector  $\mathbf{a}$ . The mixing vectors of different sources form the mixing matrix  $\mathbf{A}$

$$\mathbf{x} = \sum_i \mathbf{a}_i s_i = \mathbf{A} \mathbf{s}$$

- ▶ Knowing the mixing vector  $\mathbf{a}_i$  is not enough for recovering the source  $s_i$ .

## Problem: how to avoid interference

- ▶ The contribution of one source to the channels is called the mixing vector  $\mathbf{a}$ . The mixing vectors of different sources form the mixing matrix  $\mathbf{A}$

$$\mathbf{x} = \sum_i \mathbf{a}_i s_i = \mathbf{A} \mathbf{s}$$

- ▶ Knowing the mixing vector  $\mathbf{a}_i$  is not enough for recovering the source  $s_i$ .
- ▶ Inverse  $\mathbf{A}^{-1}$  (so-called unmixing vectors) is required and its computation requires all  $\mathbf{a}_i$ .

## Problem: how to avoid interference

- ▶ The contribution of one source to the channels is called the mixing vector  $\mathbf{a}$ . The mixing vectors of different sources form the mixing matrix  $\mathbf{A}$

$$\mathbf{x} = \sum_i \mathbf{a}_i s_i = \mathbf{A} \mathbf{s}$$

- ▶ Knowing the mixing vector  $\mathbf{a}_i$  is not enough for recovering the source  $s_i$ .
- ▶ Inverse  $\mathbf{A}^{-1}$  (so-called unmixing vectors) is required and its computation requires all  $\mathbf{a}_i$ .
- ▶ Hebbian learning can in general only recover  $\mathbf{a}_i$ , not  $\mathbf{A}^{-1}$ .

# Comparing apples and oranges

- ▶ Often it is difficult to see some target pattern in the data because it is masked by interference from some other, stronger patterns.

# Comparing apples and oranges

- ▶ Often it is difficult to see some target pattern in the data because it is masked by interference from some other, stronger patterns.
- ▶ In such cases it is particularly difficult to use simple Hebbian-type algorithms for finding the target patterns.

# Comparing apples and oranges

- ▶ Often it is difficult to see some target pattern in the data because it is masked by interference from some other, stronger patterns.
- ▶ In such cases it is particularly difficult to use simple Hebbian-type algorithms for finding the target patterns.
- ▶ Related problem: how to decide if something is large from visual image if the distance to different objects can vary?

# Comparing apples and oranges

- ▶ Often it is difficult to see some target pattern in the data because it is masked by interference from some other, stronger patterns.
- ▶ In such cases it is particularly difficult to use simple Hebbian-type algorithms for finding the target patterns.
- ▶ Related problem: how to decide if something is large from visual image if the distance to different objects can vary?
- ▶ Solution: normalise (distance in the size example, variance in Hebbian learning).

# Whitening: removing correlation structure

- ▶ Whitening (a.k.a. sphering) normalises the variance structure (data will be decorrelated and variance is isotropic = the same in every direction).

# Whitening: removing correlation structure

- ▶ Whitening (a.k.a. sphering) normalises the variance structure (data will be decorrelated and variance is isotropic = the same in every direction).
- ▶ Can be implemented by PCA + normalisation of variances.

# Whitening: removing correlation structure

- ▶ Whitening (a.k.a. sphering) normalises the variance structure (data will be decorrelated and variance is isotropic = the same in every direction).
- ▶ Can be implemented by PCA + normalisation of variances.
- ▶ The data can also be rotated “back to the original” after normalisation.

# Whitening

Result: PCA doesn't see any structure in the data but the mixing vectors become (more) orthogonal.

# Whitening in the brain

- ▶ Interestingly, decorrelation and normalisation are ubiquitous in the brain: many systems have lateral inhibition and “gain control”.

# Whitening in the brain

- ▶ Interestingly, decorrelation and normalisation are ubiquitous in the brain: many systems have lateral inhibition and “gain control”.
- ▶ For instance, retinal on-center-off-surround cells and thalamic “relay cells”.

# Whitening in the brain

- ▶ Interestingly, decorrelation and normalisation are ubiquitous in the brain: many systems have lateral inhibition and “gain control”.
- ▶ For instance, retinal on-center-off-surround cells and thalamic “relay cells”.
- ▶ Symmetric whitening computed from natural images:

# Making things different again

After whitening PCA doesn't see any structure, but what if we "disturb" the data a bit.

# Making things different again

After whitening PCA doesn't see any structure, but what if we "disturb" the data a bit.

- ▶ Remember that our target source changed slowly.  
What if we low-pass filter the data.

# Making things different again

After whitening PCA doesn't see any structure, but what if we "disturb" the data a bit.

- Remember that our target source changed slowly. What if we low-pass filter the data.

# Making things different again

After whitening PCA doesn't see any structure, but what if we "disturb" the data a bit.

- ▶ Remember that our target source changed slowly. What if we low-pass filter the data.
- ▶ Whitening was important...

# Making things different again

After whitening PCA doesn't see any structure, but what if we "disturb" the data a bit.

- ▶ Remember that our target source changed slowly. What if we low-pass filter the data.
- ▶ Whitening was important...

# Theoretical justification

- ▶ Denoising can be viewed as prior information in procedural form.

# Theoretical justification

- ▶ Denoising can be viewed as prior information in procedural form.
- ▶ DSS can be justified as an EM-algorithm for source separation: E-step = denoising using prior information, M-step = estimation of a new mixing vector.

# Theoretical justification

- ▶ Denoising can be viewed as prior information in procedural form.
- ▶ DSS can be justified as an EM-algorithm for source separation: E-step = denoising using prior information, M-step = estimation of a new mixing vector.
- ▶ Denoising can thus (but does need to) be derived from prior information  $p(\mathbf{s})$ .

# Theoretical justification

- ▶ Denoising can be viewed as prior information in procedural form.
- ▶ DSS can be justified as an EM-algorithm for source separation: E-step = denoising using prior information, M-step = estimation of a new mixing vector.
- ▶ Denoising can thus (but does need to) be derived from prior information  $p(\mathbf{s})$ .
- ▶ Whitening means that mixing vector = unmixing vector; sources can be extracted one by one.

# Nonlinear denoising

- In our example the denoising was applied to the data. This is possible only with linear denoising.

# Nonlinear denoising

- ▶ In our example the denoising was applied to the data. This is possible only with linear denoising.
- ▶ EM-connection suggests that the source estimates should be denoised. Like power method with denoising embedded in the iterations or neural PCA with denoising as the “activation function” of the neurons.

# Nonlinear denoising

- ▶ In our example the denoising was applied to the data. This is possible only with linear denoising.
- ▶ EM-connection suggests that the source estimates should be denoised. Like power method with denoising embedded in the iterations or neural PCA with denoising as the “activation function” of the neurons.
- ▶ With simple nonlinearities DSS realises independent component analysis (ICA).

# Standard methods work

- ▶ Regular PCA works for linear denoising.

# Standard methods work

- ▶ Regular PCA works for linear denoising.
- ▶ Power method required with nonlinear denoising.

# Standard methods work

- ▶ Regular PCA works for linear denoising.
- ▶ Power method required with nonlinear denoising.
- ▶ Just as PCA, DSS can be applied for very large datasets.

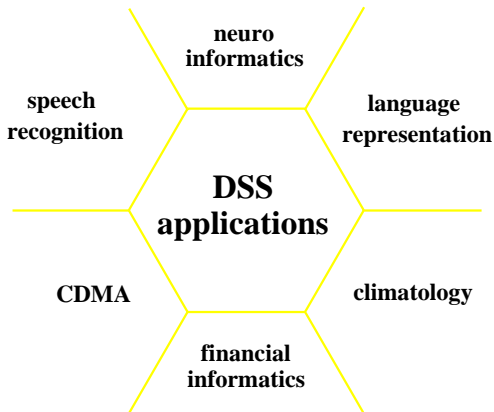

# Standard methods work

- ▶ Regular PCA works for linear denoising.
- ▶ Power method required with nonlinear denoising.
- ▶ Just as PCA, DSS can be applied for very large datasets.
- ▶ Either deflation (one-by-one extraction) or symmetric separation can be used.

# Standard methods work

- ▶ Regular PCA works for linear denoising.
- ▶ Power method required with nonlinear denoising.
- ▶ Just as PCA, DSS can be applied for very large datasets.
- ▶ Either deflation (one-by-one extraction) or symmetric separation can be used.
- ▶ Note: linear denoising + symmetric separation can only identify the signal subspace.

# DSS applications

# DSS in Climate research

Several global daily measurements during several tens of years:  
surface temperature, sea level pressure, precipitation, etc.

## DSS in Climate research

Several global daily measurements during several tens of years: surface temperature, sea level pressure, precipitation, etc.

Climatological slow components. The first is caused by the El Niño effect.

The spatial map corresponding to the El Niño component.

## Part II

### DSS in feature extraction

- **Situation:** A task, such as recognition or motor action should be performed.

## Part II

### DSS in feature extraction

- ▶ **Situation:** A task, such as recognition or motor action should be performed.
- ▶ **Task:** Find a feature representation for the situation that facilitates the task.

# PCA and DSS features from natural images

Symmetric PCA gives on-center/off-surround features.

PCA feature

activating pattern

# PCA and DSS features from natural images

Symmetric PCA gives on-center/off-surround features.

PCA feature

activating pattern

ICA-DSS gives edge-detectors resembling simple cell outputs in V1.

DSS feature

activating pattern

# Learning invariant representations

- ▶ Invariance = being insensitive to something:
  - ▶ translation
  - ▶ rotation
  - ▶ scaling
  - ▶ ...

# Learning invariant representations

- ▶ Invariance = being insensitive to something:
  - ▶ translation
  - ▶ rotation
  - ▶ scaling
  - ▶ ...
- ▶ It is as important to lose most information as to remain sensitive to the “essential features”.

## How: hierarchical grouping

- ▶ grouping of individual features.
- ▶ hierarchy of feature extraction stages.
- ▶ the higher the layer, the more complex and invariant the features.

# Hierarchies in DSS

- ▶ Stacking DSS layers does not bring anything new.

# Hierarchies in DSS

- ▶ Stacking DSS layers does not bring anything new.
- ▶ Solution: make the layer nonlinear somehow.

# Nonlinear feature expansion

Linear regression can be made nonlinear by including as inputs nonlinear functions of the inputs.

# Nonlinear feature expansion

Linear regression can be made nonlinear by including as inputs nonlinear functions of the inputs.

Many alternatives:

- ▶ **fixed nonlinearities**

# Nonlinear feature expansion

Linear regression can be made nonlinear by including as inputs nonlinear functions of the inputs.

Many alternatives:

- ▶ fixed nonlinearities
- ▶ competition and positivity constraint

# How to create expectations that drive the learning?

- ▶ The big question is: how to recognize that features belong to the same object?

# How to create expectations that drive the learning?

- ▶ The big question is: how to recognize that features belong to the same object?
- ▶ Most common criterion is temporal proximity: features that often appear roughly at the same times probably represent the same object.

# How to create expectations that drive the learning?

- ▶ The big question is: how to recognize that features belong to the same object?
- ▶ Most common criterion is temporal proximity: features that often appear roughly at the same times probably represent the same object.
- ▶ Contextual proximity is a better criterion: features that appear in the same context probably represent the same object.

# How to create expectations that drive the learning?

- ▶ The big question is: how to recognize that features belong to the same object?
- ▶ Most common criterion is temporal proximity: features that often appear roughly at the same times probably represent the same object.
- ▶ Contextual proximity is a better criterion: features that appear in the same context probably represent the same object.
- ▶ Temporal proximity is often a special case because contexts tend to evolve slowly.

# Expectation-driven learning

- ▶ inputs drive outputs.
- ▶ expectations drive learning (modulate only).
- ▶ without the nonlinear feature expansion, equivalent to canonical correlation analysis.

# Results

# Hierarchical architecture

- It makes sense to stack nonlinear feature extractors into a hierarchy.

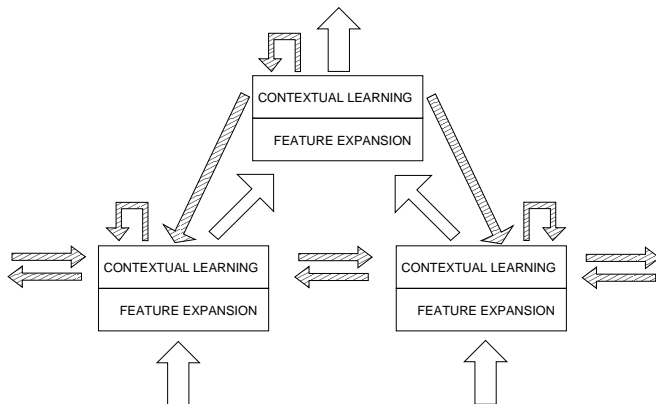

# Hierarchical architecture

- ▶ It makes sense to stack nonlinear feature extractors into a hierarchy.
- ▶ Context derived from “all over the place” can guide learning.

# Hierarchical architecture

- ▶ It makes sense to stack nonlinear feature extractors into a hierarchy.
- ▶ Context derived from “all over the place” can guide learning.
- ▶ Learning aims to find a “coherent representation of the world”.

# Hierarchical architecture

# Neocortical structure

The structure of the model discussed here is very much inspired by the neocortex:

- ▶ hierarchy of areas creating an increasingly abstract, invariant representation

# Neocortical structure

The structure of the model discussed here is very much inspired by the neocortex:

- ▶ hierarchy of areas creating an increasingly abstract, invariant representation
- ▶ excitatory-inhibitory interaction creating nonlinear “raw material”

# Neocortical structure

The structure of the model discussed here is very much inspired by the neocortex:

- ▶ hierarchy of areas creating an increasingly abstract, invariant representation
- ▶ excitatory-inhibitory interaction creating nonlinear “raw material”
- ▶ grouping simple features to get complex ones

# Neocortical structure

The structure of the model discussed here is very much inspired by the neocortex:

- ▶ hierarchy of areas creating an increasingly abstract, invariant representation
- ▶ excitatory-inhibitory interaction creating nonlinear “raw material”
- ▶ grouping simple features to get complex ones
- ▶ strong, decorrelated bottom-up stimuli

# Neocortical structure

The structure of the model discussed here is very much inspired by the neocortex:

- ▶ hierarchy of areas creating an increasingly abstract, invariant representation
- ▶ excitatory-inhibitory interaction creating nonlinear “raw material”
- ▶ grouping simple features to get complex ones
- ▶ strong, decorrelated bottom-up stimuli
- ▶ competition modulated by context

# Attention

- ▶ Attentional filtering decides which information reaches global context.
- ▶ Attention has a strong goal-directed component.
- ▶ Hypothesis: attention mediates goal information in perceptual learning.

# Attention

# Conclusion

- ▶ Basic idea in DSS: whitening or other normalisation makes learning sensitive to denoising or other such operations (e.g., combination of several datasets).

# Conclusion

- ▶ Basic idea in DSS: whitening or other normalisation makes learning sensitive to denoising or other such operations (e.g., combination of several datasets).
- ▶ DSS is flexible, robust, fast and is suitable for analysing large datasets.

# Conclusion

- ▶ Basic idea in DSS: whitening or other normalisation makes learning sensitive to denoising or other such operations (e.g., combination of several datasets).
- ▶ DSS is flexible, robust, fast and is suitable for analysing large datasets.
- ▶ With nonlinear feature expansion, DSS can be stacked in layers to get a powerful nonlinear feature extractor.

# Conclusion

- ▶ Basic idea in DSS: whitening or other normalisation makes learning sensitive to denoising or other such operations (e.g., combination of several datasets).
- ▶ DSS is flexible, robust, fast and is suitable for analysing large datasets.
- ▶ With nonlinear feature expansion, DSS can be stacked in layers to get a powerful nonlinear feature extractor.
- ▶ DSS combines attention and learning under the same framework.
