- 😊 Making modules
  
- 😊 **Arrays and array computing**
- 😊 Plotting curves and surfaces

A **list object** is a handy device for storing tabular data

- As in a sequence of objects or a table of objects

An array is another device which is very similar to a list

- Computationally more efficient
- Less flexible

When performing mathematical calculations with a computer, we often end up with a huge amount of numbers and their associated operations

- Storing numbers in lists may lead to slow programs
- Storing numbers in arrays can make them run faster

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# FdP (cont.)

This is crucial for advanced applications of mathematics in science and industry, where computer code may run for hours to weeks

Any technique that reduces execution time by some factor is important

- Focus is on clear, well-designed, and easy-to-understand code
- Then, one can start thinking about optimisation for efficiency

Arrays contribute to clear code, correctness and speed altogether

# FdP (cont.)

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

This part of the course gives an introduction to arrays

- What they can be used for
- How they are created

Vectors

Definitions, arithmetics and  
vector functions

Arrays

Numerical Python arrays

Function values

Vectorisation

Numpy arrays

# FdP (cont.)

Array computing usually ends up with a lot of numbers

It may be hard to understand what these numbers mean by only looking at them

- To understand, we visualize them

We concentrate on visualising curves that reflect functions of one variable

- Curves of the form  $y = f(x)$

We use arrays to store information about points on curves

## Vectors

vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Definitions, arithmetics and vector functions

Some mathematical quantities are associated with a set of numbers

- One example is a point in the plane

To describe the point in space, we use two coordinates (real numbers)

- We name the two coordinates of a particular point as  $x$  and  $y$
- It is common to use the notation  $(x, y)$  to denote the point
- That is, we group the numbers inside parentheses

Instead of symbols ( $x$  and  $y$ ), we may use the numbers directly

- Also  $(0, 0)$  and  $(1.5, -2.35)$  are coordinates in the plane

# Definitions, arithmetics and vector functions (cont.)

A point in a three-dimensional space has three coordinates

- We can name them  $x_1$ ,  $x_2$ , and  $x_3$

Common notation: Numbers inside parentheses,  $(x_1, x_2, x_3)$

Alternatively, we may use the symbols  $x$ ,  $y$ , and  $z$

- We write the point as  $(x, y, z)$
- Or, or we use numbers instead of symbols

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Definitions, arithmetics and vector functions (cont.)

There problems that are formulated as  $n$  equations with  $n$  unknowns

The solution of such problems contains  $n$  numbers, that we can collect inside parentheses and number from  $1$  to  $n$ , as  $(x_1, x_2, x_3, \dots, x_{n-1}, x_n)$

Quantities such as  $(x, y)$ ,  $(x, y, z)$ , or  $(x_1, \dots, x_n)$  are called **vectors**

# Definitions, arithmetics and vector functions (cont.)

Visually, a vector is an arrow that goes from the origin to a point

- Vector  $(x, y)$  is an arrow from  $(0, 0)$  to the point with coordinates  $(x, y)$  in the plane
- Vector  $(x, y, z)$  is an arrow from  $(0, 0, 0)$  to point  $(x, y, z)$  in three-dimensional space

# Definitions, arithmetics and vector functions (cont.)

In spaces with dimension  $n$  higher than three,  $(x_1, \dots, x_n)$  a vector is a point, or an arrow in  $nD$ -space from origin  $(0, \dots, 0)$  to  $(x_1, \dots, x_n)$

We say that  $(x_1, \dots, x_n)$  is a  $n$ -vector or a vector with  $n$  components

- Each of the numbers  $x_1, x_2, \dots$  is a component or an element
- We refer to the first component (or element),  
the second component (or element), ...

# Definitions, arithmetics and vector functions (cont.)

Python code may use a **list** or a **tuple objects** to represent a vector

```
1 v1 = [x, y] # list of variables
2 v2 = (-1, 2) # tuple of numbers
3 v3 = (x1, x2, x3) # tuple of variables
4
5 from math import exp
6 v4 = [exp(-i*0.1) for i in range(150)]
```

- **v1** and **v2** are vectors in the plane
- **v3** is a vector in a three-dimensional space
- **v4** is a vector in a 150D-space, values of the exponential function

# Definitions, arithmetics and vector functions (cont.)

## Remark

List/tuple objects use 0 as first index, vector  $(x_1, x_2)$  will  $(x_0, x_1)$

- This is not common in math, but here it helps making the distance from a mathematical formulation to its Python counterpart shorter

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Definitions, arithmetics and vector functions (cont.)

It is impossible to visually show what a 150D-space looks like

Going from 2D to 3D gives an idea of what it means to add dimensions

- If we forget visual perception of space, the mathematics is simple
- Going from a 4-dimensional vector to a 5-dimensional vector is as easy as adding an element to a list of symbols or numbers

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Definitions, arithmetics and vector functions (cont.)

Vectors can be viewed as arrows having a length and a direction

This makes these objects very useful in geometry and physics

- The velocity of a car has a magnitude and a direction, so has the acceleration, and the position of a point in the car is also a vector
- An edge of a triangle can be viewed as a line with direction and length

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Definition, arithmetics and vector functions (cont.)

Geometric/physical applications of vectors require operations on vectors

- We shall review some of the most important operations on vectors

The goal is not to teach computations with vectors, rather to illustrate how such computations are defined by math rules

# Definitions, arithmetics and vector functions (cont.)

## Definition

Given two vectors,  $(u_1, u_2)$  and  $(v_1, v_2)$ , we can

- add the vectors  $(u_1, u_2) + (v_1, v_2) = (u_1 + v_1, u_2 + v_2)$
- subtract them  $(u_1, u_2) - (v_1, v_2) = (u_1 - v_1, u_2 - v_2)$

## Definition

A vector  $(v_1, v_2)$  can be multiplied by a scalar  $a$

- $a \cdot (v_1, v_2) = (av_1, av_2)$

# Definitions, arithmetics and vector functions (cont.)

## Definition

The scalar product (or inner product, or dot product) between two vectors  $(u_1, u_2)$  and  $(v_1, v_2)$  is a scalar<sup>1</sup>

- $(u_1, u_2) \cdot (v_1, v_2) = u_1 v_1 + u_2 v_2$

## Definition

The length of  $(v_1, v_2)$  is  $\|(v_1, v_2)\| = \sqrt{(v_1, v_2) \cdot (v_1, v_2)} = \sqrt{v_1^2 + v_2^2}$

---

<sup>1</sup>It is often expressed as the product of the lengths of the two vectors multiplied by the cosine of the angle between them.

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Definitions, arithmetics and vector functions (cont.)

The same mathematical operations apply to  $n$ -dimensional vectors

## Remark

Instead of counting indices from **1**, as we do in math,  
from now on we count from **0**, as we do in Python

# Definition, arithmetics and vector functions (cont.)

## Definition

The addition and subtraction of two vectors with  $n$  components

$$(u_0, u_1, \dots, u_{n-1}) + (v_0, v_1, \dots, v_{n-1}) = (u_0 + v_0, \dots, u_{n-1} + v_{n-1})$$

$$(u_0, u_1, \dots, u_{n-1}) - (v_0, v_1, \dots, v_{n-1}) = (u_0 - v_0, \dots, u_{n-1} - v_{n-1})$$

## Definition

Multiplication of a vector  $(v_0, v_1, \dots, v_{n-1})$  by a scalar  $a$

$$a \cdot (v_0, v_1, \dots, v_{n-1}) = (av_0, av_1, \dots, av_{n-1})$$

# Definitions, arithmetics and vector functions (cont.)

## Definition

The inner product of two vectors  $(u_0, u_1, \dots, u_{n-1})$  and  $(v_0, v_1, \dots, v_{n-1})$

$$\begin{aligned}(u_0, u_1, \dots, u_{n-1}) \cdot (v_0, v_1, \dots, v_{n-1}) &= u_0 v_0 + u_1 v_1 + \dots + u_{n-1} v_{n-1} \\ &= \sum_{j=0}^{n-1} u_j v_j\end{aligned}$$

## Definition

The length  $\|v\|$  of the  $n$ -vector  $v = (v_0, v_1, \dots, v_{n-1})$

$$\begin{aligned}\sqrt{(v_0, v_1, \dots, v_{n-1}) \cdot (v_0, v_1, \dots, v_{n-1})} &= (v_0 v_0 + v_1 v_1 + \dots + v_{n-1} v_{n-1})^{\frac{1}{2}} \\ &= (v_0^2 + v_1^2 + \dots + v_{n-1}^2)^{\frac{1}{2}} \\ &= \left( \sum_{j=0}^{n-1} v_j^2 \right)^{\frac{1}{2}}\end{aligned}$$

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Definitions, arithmetics and vector functions (cont.)

In addition to these operations, we can define other vector operations

- These are very useful for speeding up programs

Such vector operations are rarely treated in math textbooks, yet they play a significant role in some mathematical computing environments

# Definition, arithmetics and vector functions (cont.)

## Definition

Applying a mathematical function of one variable, say  $f(x)$ , to a vector is defined as a vector where  $f$  is applied to each element

Let  $v = (v_0, \dots, v_{n-1})$  be a vector,  $f(v) = (f(v_0), \dots, f(v_{n-1}))$

## Example

The sine of vector  $v$  is vector  $\sin(v) = (\sin(v_0), \dots, \sin(v_{n-1}))$

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Definition, arithmetics and vector functions (cont.)

## Example

It follows that squaring a vector, or more generally, raising a vector to some power, can be defined as applying the operation to each element

$$v^b = (v_0^b, \dots, v_{n-1}^b)$$

# Definitions, arithmetics and vector functions (cont.)

## Definition

Another common operation between two vectors that arises in computer coding of mathematics is the 'asterisk' multiplication

$$u * v = (u_0 v_0, u_1 v_1, \dots, u_{n-1} v_{n-1})$$

## Definition

Adding a scalar  $a$  to a vector  $v$  or array is defined as adding the scalar to each component of the vector or element of the array

If  $a$  is a scalar and  $v$  a vector,  $a + v = (a + v_0, \dots, a + v_{n-1})$

# Definitions, arithmetics and vector functions (cont.)

## Example

How to compute a compound vector expression like  $v^2 * \cos(v) * e^v + 2$

We use normal rules of math, term by term, left to right, powers before multiplications and divisions, evaluated prior to addition and subtraction

- 1 First, we calculate  $v^2$ , which results in a vector  $u$
- 2 Then, we calculate  $\cos(v)$  and call the result  $p$
- 3 Then, we multiply  $u * p$  to get vector  $w$
- 4 The next step is to evaluate  $e^v$ , call the result  $q$
- 5 This is followed by the multiplication  $w * q$ , whose result is  $r$
- 6 Then, we add  $r + 2$  to get the final result

# Arrays

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

Arrays are used to represent vectors in a program

- We introduce array programming in Python

# Arrays (cont.)

First we create some lists and show how arrays differ from lists

## Example

Suppose we have some function  $f(x)$ , we want to evaluate it at a number  $n$  of points  $x_0, \dots, x_{n-1}$

- We could collect all  $n$  pairs  $(x_i, f(x_i))$  in a list, for  $i = 0, \dots, n - 1$
- We could collect all  $x_i$  values and all  $f(x_i)$  values in two lists, for  $i = 0, \dots, n - 1$

## Arrays (cont.)

An interactive session shows how to create these lists

```
1 >>> def f(x):  
2     ... return x**3 # sample function  
3     ...  
4  
5 >>> n = 5 # no of points along the x axis  
6 >>> dx = 1.0/(n-1) # spacing between x points in [0,1]  
7  
8 >>> xlist = [i*dx for i in range(n)]  
9 >>> ylist = [f(x) for x in xlist]  
10  
11 >>> pairs = [[x, y] for x, y in zip(xlist, ylist)]
```

Here, the list elements consist of objects that are of the same type

- Any element in `pairs` is a list of two `float` objects
- Any element in `xlist` or `ylist` is a `float` object

### Remark

We used list comprehensions for compactness

#### Vectors

Definitions, arithmetics and  
vector functions

Function values

Vectorisation

#### Numpy arrays

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Arrays (cont.)

## Remark

Lists are more flexible than that, because elements can be any object

```
1 mylist = [2, 6.0, 'tmp.pdf', [0,1]]
```

`mylist` holds an `int`, a `float`, a `string`, and a `list object`

- The combination of object types gives heterogeneous lists

We can remove/add elements from a list, anywhere in the list

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Arrays (cont.)

This flexibility of lists is in general convenient to have as a programmer

- In cases where all elements are of the same type and the number of elements is fixed, arrays can be used instead

The benefits of arrays are faster computations, less memory demands

- Extensive support for mathematical operations on data

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Arrays (cont.)

Because of greater efficiency/convenience, arrays are largely used

- Arrays are prominent in other programming languages

Lists are the choice when we need the flexibility of adding/removing elements or when the elements may be of different object types

Vectors

Definitions, arithmetics and  
vector functions

Arrays

**Numerical Python arrays**

Numpy arrays

# Numerical Python arrays

## Arrays

Vectors

Definitions, arithmetics and  
vector functions

Arrays

Numerical Python arrays

Function values

Vectorisation

Numpy arrays

# Numerical Python arrays (cont.)

An **array object** can be viewed as a variant of a list

- All elements must be of the same type (preferably integer, real, or complex numbers), for efficient numerical computing and storage
- The number of elements must be known when the array is created <sup>2</sup>
- Arrays with one index are often called vectors
- Arrays with two indices are used as an efficient data structure for tables, instead of lists of lists
- Arrays can also have three or more indices

---

<sup>2</sup>The number of elements in an array can be changed, at a large computational cost

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Numerical Python arrays (cont.)

Arrays are not in Python, package Numerical Python (**numpy**) is needed

- With **numpy**, a wide range of math operations can be done directly on arrays (no need for loops over array elements)
- This process is commonly called **vectorization**

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Numerical Python arrays (cont.)

## Remark

There is an actual object type called **array** in standard Python

- This data type is not so efficient for math computations

# Numerical Python arrays (cont.)

The standard import statement for Numerical Python

```
1 import numpy as np
```

## Example

To convert a list `r` to an array `a`, we use `function array` from `numpy`

```
1 a = np.array(r)
```

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Numerical Python arrays (cont.)

## Example

To create a new array of length `n` which is filled with zeros

```
1 a = np.zeros(n)
```

By default, the array elements are `float objects`

- To specify elements of a different type (e.g., zeros that are `int objects`), a second argument can be given

# Numerical Python arrays (cont.)

## Example

Function `zeros_like` generates an array of zeros where the length is that of the array `c` and the element type is the same as those in `c`

```
1 a = np.zeros_like(c)
```

## Example

An array of `n` elements equally spaced in an interval `[p,q]`

- The `numpy` function `linspace` creates such an array

```
1 a = np.linspace(p, q, n)
```

# Numerical Python arrays (cont.)

Array elements are accessed by square brackets as for lists: `a[i]`

Slices also work as for lists

- `a[1:-1]` picks all elements of `a` except the first and the last
- Contrary to lists, `a[1:-1]` is NOT a copy of the data in `a`

## Example

```
1 a = np.zeros(n)
2
3 b = a[1:-1]
4 b[2] = 0.1
```

The second instruction will change `b[2]` and also `a[3]` to `0.1`

Vectors

Definitions, arithmetics and  
vector functions

Arrays

Numerical Python arrays

Function values

Vectorisation

Numpy arrays

# Numerical Python arrays (cont.)

A slice `a[i:j:s]` picks the elements starting with index `i`, stepping `s` indices at the time up to, but not including, `j`

- Omitting `i` implies `i=0`
- Omitting `j` implies `j=n`, if `n` is the number of elements in the array

## Example

`a[0:-1:2]` picks every two elements up to, but not including, the last element, while `a[::4]` picks every four elements in the whole array

# Numerical Python arrays (cont.)

## Remark

```
1 import numpy as np
```

This statement with subsequent prefixing of NumPy functions/variables by `np`, is standard syntax in the Python scientific computing community

```
1 from numpy import *
```

To make Python programs look closer to MATLAB and ease transition to/from that language, this statement is used to remove the prefix

- This is the present standard in interactive Python shells

## Example

For  $f(x) = \sinh(x - 1) * \sin(wt)$

```
1 from numpy import sinh, sin
2
3 def f(x):
4     return sinh(x-1)*sin(w*t)
```

Vectors

Definitions, arithmetics and  
vector functions

Arrays

Numerical Python arrays

**Function values**

Vectorisation

Numpy arrays

# Function values

## Arrays

# Function values

With basic operations, we can make arrays from lists `xlist` and `ylist`

## Example

```
1 >>> def f(x):
2   ... return x**3
3
4 >>> n = 5
5 >>> dx = 1.0/(n-1)
6
7 >>> xlist = [i*dx for i in range(n)]
8 >>> ylist = [f(x) for x in xlist]
9
10
11 >>> import numpy as np
12 >>> x2 = np.array(xlist)           # turn list xlist into array x2
13 >>> y2 = np.array(ylist)         # turn list ylist into array y2
14
15 >>> x2
16     array([0., 0.25, 0.5, 0.75, 1.])
17
18 >>> y2
19     array([0., 0.015625, 0.125, 0.421875, 1.])
```

# Function values

Making a list and then converting the list to an array is not optimal

We can compute the arrays directly

- The equally spaced coordinates in `x2` can be computed by the `np.linspace` function
- The `y2` array can be first created by `np.zeros`, to ensure that `y2` has the right length `len(x2)`
- Then, we can run a **FOR-loop** to fill in all elements in `y2` with `f` values

```
1 >>> def f(x):
2   ... return x**3
3
4 >>> n = len(xlist)
5 >>> x2 = np.linspace(0, 1, n)
6
7 >>> y2 = np.zeros(n)
8 >>> for i in xrange(n):           # xrange vs range
9   ... y2[i] = f(x2[i])
10
11 >>> y2
12 array([ 0. , 0.015625, 0.125 , 0.421875, 1. ])
```

## Function values (cont.)

In the **FOR-loop**: `xrange` instead of `range`

### Remark

The former (`xrange`) is faster for long loops because it avoids generating and storing a list of integers, as it generates the values one by one

- For loops over long arrays, `xrange` is preferable over `range`

In Python version 3.x, `range` is the same as `xrange`

Creating an array of a given length is referred to as **allocating** the array

- Part of the computer's memory (RAM) is marked for being occupied by the array
- Arrays can fill up most of the memory

# Function values (cont.)

## Example

To shorten the code, create the `y2` data in a **list comprehension**

```
1 >>> x2 = np.linspace(0, 1, n)
2
3 >>> y2 = np.array([f(xi) for xi in x2])
```

- **List comprehensions** produce lists, not arrays
- Transform **list objects** to **array objects**

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

**Vectorisation**

Numpy arrays

# Vectorisation

## Arrays

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Vectorisation

A great advantage with arrays is that we can eliminate loops

- Loops over very long arrays may run slowly
- We can apply `f` directly to the whole array

```
1 >>> def f(x):  
2   ... return x**3  
3  
4 >>> x2  
5   array([ 0. , 0.25, 0.5 , 0.75, 1. ])  
6  
7 >>> y2 = f(x2)  
8  
9 >>> y2  
10  array([ 0. , 0.015625, 0.125 , 0.421875, 1. ])
```

# Vectorisation (cont.)

## Remark

Instead of calling  $f(x_2)$ , we can write the formula `x2**3` directly

The important point is that `numpy` implements vector arithmetics

- For arrays of arbitrary dimensions

Also, `numpy` provides its own versions of mathematical functions

- `cos`, `sin`, `exp`, `log`, ...

So, with array arguments, the function is applied to each element

# Vectorisation (cont.)

This code computes each array element separately

## Example

```
1 from math import sin, cos, exp
2 import numpy as np
3
4 x = np.linspace(0, 2, 201)
5
6 r = np.zeros(len(x))
7 for i in xrange(len(x)):
8     r[i] = sin(np.pi*x[i])*cos(x[i])*exp(-x[i]**2)+2+x[i]**2
```

Vectors

Definitions, arithmetics and  
vector functions

Arrays

Numerical Python arrays

Function values

Vectorisation

Numpy arrays

# Vectorisation (cont.)

This version of the code operates on arrays directly

## Example

```
1 x = np.linspace(0, 2, 201)
2
3 r = np.sin(np.pi*x)*np.cos(x)*np.exp(-x**2)+2*x**2
```

Equivalently, without the `np` prefix

```
1 from numpy import sin, cos, exp, pi
2
3 r = sin(pi*x)*cos(x)*exp(-x**2)+2*x**2
```

Vectorisation

Numpy arrays

# Vectorisation (cont.)

## Remark

It is important to understand that the `sin function` from `math module` is different from the `sin function` provided by `numpy`

- The former does not allow array arguments
- The latter accepts real numbers and arrays

## Vectorisation (cont.)

Replacing a loop for computing  $r[i]$  with a vector/array expression as  $\sin(x)*\cos(x)*\exp(-x**2) + 2 + x**2$  is called **vectorization**

```
1 r = sin(pi*x)*cos(x)*exp(-x**2) + 2 + x**2
```

The loop version can be referred to as **scalar code**

```
1 x = np.linspace(0, 2, 201)
2
3 r = np.zeros(len(x))
4 for i in xrange(len(x)):
5     r[i] = sin(np.pi*x[i])*cos(x[i])*exp(-x[i]**2)+2+x[i]**2
```

# Vectorisation (cont.)

## Example

### Scalar version

```
1 import numpy as np
2 import math
3
4 x = np.zeros(N); y = np.zeros(N)
5 dx = 2.0/(N-1) # spacing of x coordinates
6
7 for i in range(N):
8     x[i] = -1 + dx*i
9     y[i] = math.exp(-x[i])*x[i]
```

### Vector version

```
1 x = np.linspace(-1, 1, N)
2 y = np.exp(-x)*x
```

Vectors

Definitions, arithmetics and  
vector functions

Arrays

Numerical Python arrays

Function values

Vectorisation

Numpy arrays

# Vectorisation (cont.)

**List comprehension** result in scalar code, as there are explicit **FOR-loops** operating on scalar quantities

```
1 x = array([-1 + dx*i for i in range(N)])  
2 y = array([np.exp(-xi)*xi for xi in x])
```

The requirement of vectorised code is that there are NO explicit Python **FOR-loops**

## Remark

In the **numpy** package, the loops to compute array elements are performed in fast C/Fortran code :)

## Vectorisation (cont.)

**Functions** for scalar arguments automatically work for array arguments provided the inner **functions** in the definition accept array arguments

### Example

```
1 def f(x):  
2     return x**4*exp(-x)  
3  
4 x = np.linspace(-3, 3, 101)  
5 y = f(x)
```

**Function** `exp` must be imported as `from numpy import *`

- Or explicitly as `from numpy import exp`

One can prefix `exp` as in `np.exp` (less attractive math syntax)

Vectors

Definitions, arithmetics and  
vector functions

Arrays

Numerical Python arrays

Function values

Vectorisation

Numpy arrays

# Vectorisation (cont.)

When **function**  $f(x)$  works with array arguments  $x$ ,  $f$  is vectorised

Provided the math expressions in  $f$  involve arithmetic operations and basic math functions from **math module**,  $f$  will be automatically vectorised by importing the **functions** from **numpy** instead of **math**

- Note true if the expressions inside  $f$  involve **IF-tests**
- To work with arrays, that code need to be re-written

## Remark

Vectorisation helps speeding up code performing computations on arrays

Moreover, vectorisation gives more compact code, which is easier to read

## Numpy arrays

# Copying arrays

## Numpy arrays

# Copying arrays (cont.)

## Example

Let `x` be an array, changing `a` will also affect `x`

```
1 >>> import numpy as np
2
3 >>> x = np.array([1, 2, 3.5])
4
5 >>> a = x
6 >>> a[-1] = 3                # this changes x[-1] too!
7
8 >>> x
9     array([ 1.,  2.,  3.]
```

Statement `a = x` makes `a` refer to the same array as `x`

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Copying arrays (cont.)

## Example

Changing **a** without changing **x** requires **a** to be a copy of **x**

```
1 >>> a = x.copy()
2 >>> a[-1] = 9
3
4 >>> a
5     array([ 1.,  2.,  9.])
6
7 >>> x
8     array([ 1.,  2.,  3.])
```

# In-place arithmetics

## Numpy arrays

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# In-place arithmetics

Let  $a$  and  $b$  be two arrays of the same shape

- The expression  $a += b$  means  $a = a + b$

In the statement  $a = a + b$ , the sum  $a + b$  is first computed, this yields a new array, and then the name  $a$  is bound to this new array

- Old array  $a$  is lost, unless there are other names assigned to it

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# In-place arithmetics

In  $a += b$ , elements of  $b$  are added directly to the elements of  $a$

- There is no hidden intermediate array as in  $a = a + b$

This implies that  $a += b$  is more efficient than  $a = a + b$

- As Python avoids making an extra array

Operators  $+=$ ,  $*=$ , etc perform **in-place arithmetics** on arrays

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# In-place arithmetics (cont.)

On the computation of a compound array expression

## Example

```
1 a = (3*x**4 + 2*x + 4)/(x + 1)
```

①  $r1 = x^{**}4$

②  $r2 = 3*r1$

③  $r3 = 2*x$

④  $r4 = r2 + r3$

⑤  $r5 = r4 + 4$

⑥  $r6 = x + 1$

⑦  $r7 = r5/r6$

⑧  $a = r7$

# In-place arithmetics (cont.)

```
1 a = (3*x**4 + 2*x + 4)/(x + 1)
```

- A significantly less readable code

```
1 a = x.copy()
2 a **= 4
3 a *= 3
4 a += 2*x
5 a += 4
6 a /= x + 1
```

# In-place arithmetics (cont.)

```
1 a = (3*x**4 + 2*x + 4)/(x + 1)
```

-	• a = x.copy()
• r1 = x**4	• a **= 4
• r2 = 3*r1	• a *= 3
• r3 = 2*x	-
• r4 = r2 + r3	• a += 2*x
• r5 = r4 + 4	• a += 4
• r6 = x + 1	-
• r7 = r5/r6	• a /= x + 1
• a = r7	-

With in-place arithmetics we can save creating three new arrays

- The three arrays are from copying `a` and computing the RHS `2*x` and `x+1`

Function values

Vectorisation

## Numpy arrays

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# In-place arithmetics (cont.)

## Remark

Often in computational sciences, a large number of arithmetics is performed on big arrays, saving memory/array allocation time

- In-place arithmetics becomes important

# In-place arithmetics (cont.)

Mixing up assignment and in-place arithmetics makes it easier (worse) to make unintended changes to more than one array

## Example

This code changes `x`, as `a` refers to the same array as `x`

```
1 a = x  
2 a += y
```

- The change of `a` is done in-place

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Array allocation

## Numpy arrays

# Array allocation

Function `np.zeros` is handy for making a new array `a` of given size

- Often size and type of array elements have to match some existing array `x`

We can either copy the original array

```
1 a = x.copy()
```

or, we can fill in new elements in `a`

```
1 a = np.zeros(x.shape, x.dtype)
```

Attribute `x.dtype` holds the array element type (`dtype` for data type), `x.shape` is a tuple with the array dimensions

- Variable `a.ndim` holds the number of dimensions

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Array allocation (cont.)

The `np.asarray` function turns an object into an array

```
1 a = np.asarray(a)
```

Nothing is copied if `a` is already is an array

If `a` is a list or tuple, a new array with a copy of the data is created

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Generalised indexing

Slices can be used to extract and manipulate subarrays

The slice `f:t:i` corresponds to the index set

- `f, f+i, f+2*i, ...` up to, but not including, `t`

Such an index set can be given explicitly too

- `a[range(f,t,i)]`

The integer list from `range` can be used as a set of indices

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Generalised indexing (cont.)

Any integer list or integer array can be used as index

```
1 >>> a = np.linspace(1, 8, 8)
2 >>> a
3     array([ 1.,  2.,  3.,  4.,  5.,  6.,  7.,  8.])
4
5 >>> a[[1,6,7]] = 10
6 >>> a
7     array([ 1., 10.,  3.,  4.,  5.,  6., 10., 10.])
8
9
10 >>> a[range(2,8,3)] = -2           # same as a[2:8:3] = -2
11 >>> a
12     array([ 1., 10., -2.,  4.,  5., -2., 10., 10.])
```

## Generalised indexing (cont.)

We can also use boolean arrays to generate an index set

- The indices in the set correspond to indices for which the boolean array has **True** values

### Example

```
1 >>> a[a < 0]           # pick out the negative elements of a
2     array([-2., -2.])
3
4
5 >>> a[a < 0] = a.max()
6 >>> a
7     array([ 1., 10., 10., 4., 5., 10., 10., 10.])
8
9
10 >>>                   # Replace elements where a is 10 by the first
11 >>>                   # elements from another array/list
12 >>> a[a == 10] = [10, 20, 30, 40, 50, 60, 70]
13 >>> a
14     array([ 1., 10., 20., 4., 5., 30., 40., 50.])
```

# Array type, generation and manipulation

## Numpy arrays

## Vectors

Definitions, arithmetics and  
vector functions

## Arrays

Numerical Python arrays

Function values

Vectorisation

## Numpy arrays

# Array type, generation and manipulation

To check an object's type, it is possible to use the `type` function

- In case of a `numpy` array, the type is a `ndarray` object

## Example

```
1 >>> a = np.linspace(-1, 1, 3)
2 >>> a
3     array([-1.,  0.,  1.])
4
5 >>> type(a)
6     <type 'numpy.ndarray'>
```

## Array type, generation and manipulation (cont.)

To check if a variable is a `ndarray` or a `float` or a `int` object

- It is possible to use function `isinstance`

### Example

```
1 >>> isinstance(a, np.ndarray)
2     True
3
4 >>> isinstance(a, (float, int))           # float or int?
5     False
```

# Array type and generation (cont.)

## Example

Suppose we have some constant function and we want to vectorise it

```
1 def f(x):  
2     return 2
```

The function accepts an array argument `x` and returns a `float object`

- The vectorised version should return an array of the same shape of `x`, with each element equal `2`

```
1 def fv(x):  
2     return np.zeros(x.shape, x.dtype) + 2
```

Yet, an optimal function works with both scalar and array arguments

# Array type and generation (cont.)

To handle this possibility, we must test for the argument type

```
1 def f(x):
2     if isinstance(x, (float, int)):
3         return 2
4
5     elif isinstance(x, np.ndarray):
6         return np.zeros(x.shape, x.dtype) + 2
7
8     else:
9         raise TypeError\
10      ('x must be int, float or ndarray, not %s' % type(x))
```

## Array type and generation (cont.)

A special compact syntax `r_[f:t:s]` for the `linspace` function

### Example

```
1 >>> a = r_[-5:5:11j]           # same as linspace(-5, 5, 11)
2 >>> print a
3 [-5. -4. -3. -2. -1.  0.  1.  2.  3.  4.  5.]
```

- `11j`: 11 elements (between `-5` and `5`, including upper limit `5`)
- That is, the number of elements in the array is given with the imaginary number syntax

## Numpy arrays

# Shape manipulation

The `shape` attribute in `array objects` holds the shape

- The size of each dimension of an array

`Function size` returns the total number of elements

## Example

```
1 >>> a = np.linspace(-1, 1, 6)
2 >>> print a
3     [-1. -0.6 -0.2  0.2  0.6  1. ]
4
5 >>> a.shape
6     (6,)
7

## Numpy arrays

A few equivalent ways of changing the shape of an array

```
1 >>> print a
2      [-1. -0.6 -0.2  0.2  0.6  1. ]
3
4 >>> a.shape = (2, 3)
5 >>> a = a.reshape(2, 3)           # alternative
6 >>> a.shape
7      (2, 3)
8
9 >>> print a
10     [[-1.  -0.6  -0.2]
11      [ 0.2   0.6   1. ]]
12
13 >>> a.size           # total no of elements
14     6
15
16 >>> len(a)          # no of rows
17     2
18
19 >>> a.shape = (a.size,)      # reset shape
```
